**Summary.** — Large gaps in labor productivity between the traditional and modern parts of the economy are a fundamental reality of developing societies. In this paper, we document these gaps, and emphasize that labor flows from low-productivity activities to high-productivity activities are a key driver of development. Our results show that since 1990 structural change has been growth reducing – with labor moving from low – to high- productivity sectors - in both Africa and Latin America, with the most striking changes taking place in Latin America. Our results also show that things seem to be turning around in Africa: after 2000, structural change contributed positively to Africa’s overall productivity growth. For Africa, these results are encouraging. Moreover, the very low levels of productivity and industrialization across most of the continent indicate an enormous potential for growth through structural change.

*Key words* — Africa, structural change, productivity growth

## 1. INTRODUCTION

One of the earliest and most central insights of the literature on economic development is that development entails structural change. The countries that manage to pull out of poverty and get richer are those that are able to diversify away from agriculture and other traditional products. As labor and other resources move from agriculture into modern economic activities, overall productivity rises and incomes expand. The speed with which this structural transformation takes place is the key factor that differentiates successful countries from unsuccessful ones.

Developing economies are characterized by large productivity gaps between different parts of the economy. Dual economy models à la W. Arthur Lewis have typically emphasized productivity differentials between broad sectors of the economy, such as the traditional (rural) and modern (urban) sectors. More recent research has identified significant differentials within modern, manufacturing activities as well. Large productivity gaps can exist even among firms and plants within the same industry. Whether between plants or across sectors, these gaps tend to be much larger in developing countries than in advanced economies. They are indicative of the allocative inefficiencies that reduce overall labor productivity.

The upside of these allocative inefficiencies is that they can potentially be an important engine of growth. When labor and other resources move from less productive to more productive activities, the economy grows even if there is no productivity growth *within* sectors. This kind of growth-enhancing structural change can be an important contributor to overall economic growth. High-growth countries are

typically those that have experienced substantial growth-enhancing structural change. As we shall see, the bulk of the difference between Asia’s recent growth, on the one hand, and Latin America’s and Africa’s, on the other, can be explained by the variation in the contribution of structural change to overall labor productivity. Indeed, one of the most striking findings of this paper is that in many Latin American and Sub-Saharan African countries, broad patterns of structural change have served to *reduce* rather than increase economic growth since 1990.

Developing countries, almost without exception, have become more integrated with the world economy since the early 1990s. Industrial tariffs are lower than they ever have been and foreign direct investment flows have reached new heights. Clearly, globalization has facilitated technology transfer and contributed to efficiencies in production. Yet the very diverse outcomes we observe among developing countries suggest that the consequences of globalization depend on the *manner* in which countries integrate into the global economy. In several cases—most notably China, India, and some other Asian

\* The bulk of this paper was previously published as “Globalization, Structural Change and Productivity Growth” in *Making Globalization Socially Sustainable* (Geneva: International Labour Organization and World Trade Organization, 2011), chapter 2. This version updates that paper with recent results on Africa. We are grateful to Marion Jansen for guidance and to seminar participants and colleagues for useful comments. countries—globalization’s promise has been fulfilled. High-productivity employment opportunities have expanded and structural change has contributed to overall growth. But in many other cases—in Latin America and Sub-Saharan Africa—globalization appears not to have fostered the desirable kind of structural change. Labor has moved in the *wrong* direction, from more productive to less productive activities, including, most notably, informality.

This conclusion would seem to be at variance with a large body of empirical work on the productivity-enhancing effects of trade liberalization. For example, study after study shows that intensified import competition has forced manufacturing industries in Latin America and elsewhere to become more efficient by rationalizing their operations.<sup>1</sup> Typically, the least productive firms have exited the industry, while remaining firms have shed “excess labor.” It is evident that the top tier of firms has closed the gap with the technology frontier—in Latin America and Africa, no less than in East Asia. However, the question left unanswered by these studies is what happens to the workers who are thereby displaced. In economies that do not exhibit large inter-sectoral productivity gaps or high and persistent unemployment, labor displacement would not have important implications for economy-wide productivity. In developing economies, on the other hand, the prospect that the displaced workers would end up in even lower-productivity activities (services, informality) cannot be ruled out. That is indeed what seems to have typically happened in Latin America and Africa. An important advantage of the broad, general-equilibrium approach we take in this paper is that it is able to capture changes in inter-sectoral allocative efficiency as well as improvements in within-industry productivity.

Our results for Africa are especially puzzling. The countries in Africa are by far the poorest countries in the world and thus stand to gain the most from structural transformation. Moreover, the fact that structural change in Africa was growth reducing during 1990–2005 seems at odds with Africa’s much touted economic success in recent years. The start of the 21st century saw the dawn of a new era in which African economies grew as fast or faster than the rest of the world. To better understand the results for Africa, in this update we decompose our analysis into two periods: 1990–1999 and 2000 onward. The latter period corresponds to what many have dubbed the “African Growth Miracle” and to a surge in global commodity prices. Our results for the period 2000 onward are notably different for Africa from those reported in the original version of this paper (McMillan & Rodrik, 2011). From 2000 onward, we show that structural change contributed positively to Africa’s overall growth accounting for nearly half of it.<sup>2</sup> We also find that in over half of the countries in our Africa sample, structural change coincided with some expansion of the manufacturing sector (albeit the magnitudes are small) indicating that these economies may be becoming less vulnerable to commodity price shocks. For the other regions, the results do not differ significantly across periods.

In our empirical work, we identify three factors that help determine whether (and the extent to which) structural change goes in the right direction and contributes to overall productivity growth. First, economies with a revealed comparative advantage in primary products are at a disadvantage. The larger the share of natural resources in exports, the smaller the scope of productivity-enhancing structural change. The key here is that minerals and natural resources do not generate much employment, unlike manufacturing industries and related services. Even though these “enclave” sectors typically operate at very high productivity, they cannot absorb the surplus labor from agriculture.

Second, we find that countries that maintain competitive or undervalued currencies tend to experience more growth-enhancing structural change. This is in line with other work that documents the positive effects of undervaluation on modern, tradable industries (Rodrik, 2008). Undervaluation acts as a subsidy on those industries and facilitates their expansion.

Finally, we also find evidence that countries with more flexible labor markets experience greater growth-enhancing structural change. This also stands to reason, as rapid structural change is facilitated when labor can flow easily across firms and sectors. By contrast, we do not find that other institutional indicators, such as measures of corruption or the rule of law, play a significant role.

The remainder of the paper is organized as follows. Section 3 describes our data and presents some stylized facts on economy-wide gaps in labor productivity. The core of our analysis is contained in Section 3, where we discuss patterns of structural change in Africa, Asia, and Latin America since 1990. Section 4 focuses on explaining why structural change has been growth-enhancing in some countries and growth-reducing in others. Section 5 offers final comments. The Appendix provides further details about the construction of our data base.

## 2. THE DATA AND SOME STYLIZED FACTS

Our data base consists of sectoral and aggregate labor productivity statistics for 38 countries, covering the period up to 2005. Of the countries included, 29 are developing countries and nine are high-income countries. The countries and their geographical distribution are shown in Table 1, along with some summary statistics.

In constructing our data, we took as our starting point the Groningen Growth and Development Center (GGDC) data base, which provides employment and real valued added statistics for 27 countries disaggregated into 10 sectors (Timmer & de Vries, 2007, 2009).<sup>3</sup> The GGDC dataset does not include any African countries or China. Therefore, we collected our own data from national sources for an additional 11 countries, expanding the sample to cover several African countries, China, and Turkey (another country missing from the GGDC sample). In order to maintain consistency with the GGDC Database data, we followed, as closely as possible, the procedures on data compilation followed by the GGDC authors.<sup>4</sup> For purposes of comparability, we combined two of the original sectors (Government Services and Community, Social, and Personal Services) into a single one, reducing the total number of sectors to nine. We converted local currency value added at 2000 prices to dollars using 2000 PPP exchange rates. Labor productivity was computed by dividing each sector’s value added by the corresponding level of sectoral employment. We provide more details on our data construction procedures in the Appendix. The sectoral breakdown we shall use in the rest of the paper is shown in Table 2.

A big question with data of this sort is how well they account for the informal sector. Our data for value added come from national accounts, and as mentioned by Timmer and de Vries (2007), the coverage of such data varies from country to country. While all countries make an effort to track the informal sector, obviously the quality of the data can vary greatly. On employment, Timmer and de Vries’ strategy is to rely on household surveys (namely, population censuses) for total employment levels and their sectoral distribution, and use labor force surveys for the growth in employment between census years. Census data and other household surveys tend to

have more complete coverage of informal employment. In short, a rough characterization would be that the employment numbers in our dataset broadly coincide with actual employment levels regardless of formality status, while the extent to which value added data include or exclude the informal sector heavily depends on the quality of national sources.

The countries in our sample range from Malawi, with an average labor productivity of \$1,354 (at 2000 PPP dollars), to the United States, where labor productivity is more than 50 times as large (\$70,235). They include nine African countries, nine Latin American countries, ten developing Asian countries, one Middle Eastern country, and nine high-income countries. China is the country with the fastest overall productivity growth rate (8.8% per annum during 1990–2005). At the other extreme, Kenya, Zambia, Malawi, and Venezuela have experienced negative productivity growth rates over the same period.

As Table 1 shows, labor productivity gaps between different sectors are typically very large in developing countries. This is particularly true for poor countries with mining enclaves, where few people tend to be employed at very high labor

productivity. In Malawi, for example, labor productivity in mining is 136 times larger than that in agriculture! In fact, if only all of Malawi's workers could be employed in mining, Malawi's labor productivity would match that of the United States. Of course, mining cannot absorb many workers, and neither would it make sense to invest in so much physical capital across the entire economy.

It may be more meaningful to compare productivity levels across sectors with similar potential to absorb labor, and here too the gaps can be quite large. We see a typical pattern in Turkey, which is a middle-income country with still a large agricultural sector (Figure 1). Productivity in construction is more than twice the productivity in agriculture, and productivity in manufactures is almost three times as large. The average manufactures-agriculture productivity ratio is 2.3 in Africa, 2.8 in Latin America, and 3.9 in Asia. Note that the productivity-disadvantage of agriculture does not seem to be largest in the poorest countries, a point to which we will return below.

On the whole, however, inter-sectoral productivity gaps are clearly a feature of underdevelopment. They are widest for the

Note: The coefficient of variation in sectoral labor productivities within countries (vertical axis) is graphed against the log of the countries' average labor productivity (horizontal axis), both in 2005.

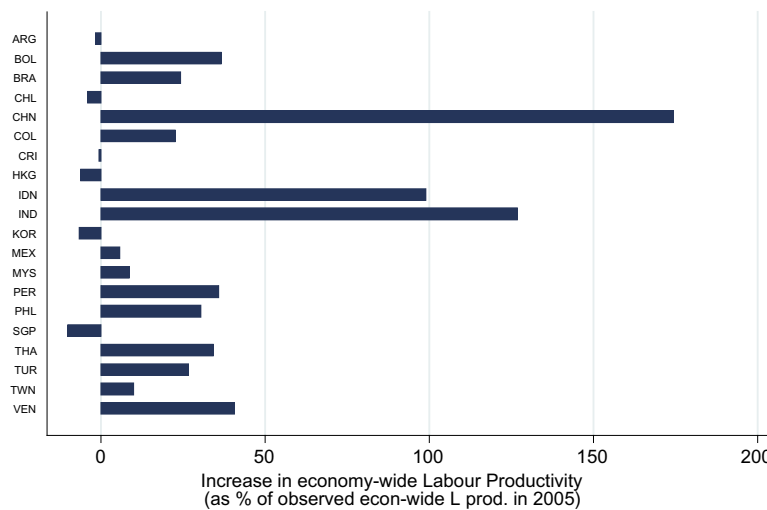

Figure 2. Relationship between inter-sectoral productivity gaps and income levels.

poorest countries in our sample and tend to diminish as a result of sustained economic growth. Figure 2 shows how a measure of economy-wide productivity gaps, the coefficient of variation of the log of sectoral labor productivities, declines over the course of development. The relationship between this measure and the average labor productivity in the country is negative and highly statistically significant. The figure underscores the important role that structural change plays in producing convergence, both within economies and across poor and rich countries. The movement of labor from low-productivity to high-productivity activities raises economy-wide labor productivity. Under diminishing marginal products, it also brings about convergence in economy-wide labor productivities.

The productivity gaps described here refer to differences in average labor productivity. When markets work well and structural constraints do not bind, it is productivities at the margin that should be equalized. Under a Cobb-Douglas production

function specification, the marginal productivity of labor is the average productivity multiplied by the labor share. So if labor shares differ greatly across economic activities comparing average labor productivities can be misleading. The fact that average productivity in public utilities is so high (see Table 2), for example, may simply indicate that the labor share of value added in this capital-intensive sector is quite small. But in the case of other sectors it is not clear that there is a significant bias. Once the share of land is taken into account, for example, it is not obvious that the labor share in agriculture is significantly lower than in manufacturing (Mundlak, Butzer, & Larson, 2008). So the 2–4-fold differences in average labor productivities between manufacturing and agriculture do point to large gaps in marginal productivity.

Another way to emphasize the contribution of structural change is to document how much of the income gap between rich and poor countries is accounted for by differences in economic structure as opposed to differences in productivity levels

Note: This figure shows the percent increase in economy-wide average labor productivity obtained under the assumption that the inter-sectoral composition of the labor force matches the pattern observed in the rich countries.

Figure 3. Counterfactual impact of changed economic structure on economy-wide labor productivity, non-African countries.

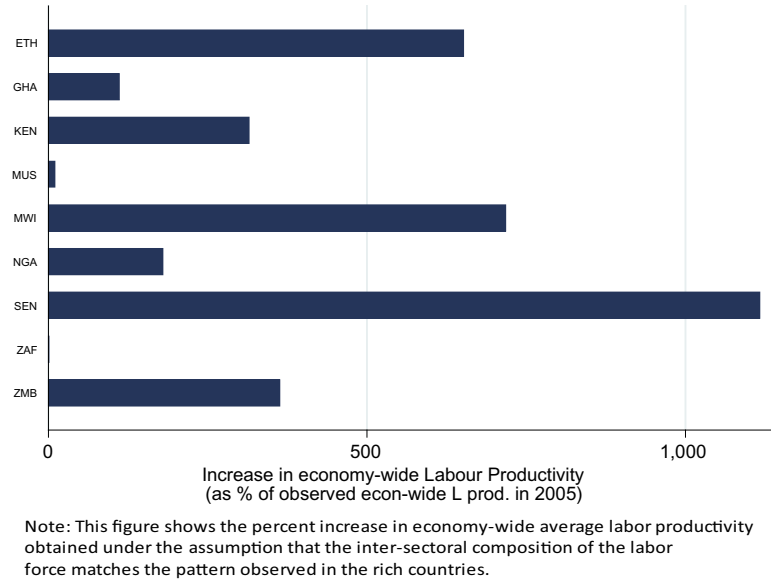

Figure 4. Counterfactual impact of changed economic structure on economy-wide labor productivity, African countries.

Note: Economy-wide labor productivity shown on the horizontal axis. Ratio of agricultural productivity to non-agricultural productivity (in percent) shown on vertical axis. Full panel.

Figure 5. Relationship between economy-wide labor productivity and ratio of agricultural to non-agricultural productivity.

within sectors. Since even poor economies have some industries that operate at high levels of productivity, it is evident that these economies would get a huge boost if such industries could employ a much larger share of the economy’s labor force. The same logic applies to broad patterns of structural change as well, captured by our 9-sector classification.

Consider the following thought experiment. Suppose that sectoral productivity levels in the poor countries were to remain unchanged, but that the inter-sectoral distribution of employment matched what we observe in the advanced economies.<sup>5</sup> This would mean that developing countries would employ a lot fewer workers in agriculture and a lot more in their modern, productive sectors. We assume that these changes in employment patterns could be achieved without any change (up or down) in productivity levels within individual sectors.

What would be the consequences for economy-wide labor productivity? Figures 3 and 4 show the results for the non-African and African samples, respectively.

The hypothetical gains in overall productivity from sectoral reallocation, along the lines just described, are quite large, especially for the poorer countries in the sample. India’s average productivity would more than double, while China’s would almost triple (Figure 3). The potential gains are particularly large for several African countries, which is why those countries are shown on a separate graph using a different scale. Ethiopia’s productivity would increase six-fold, Malawi’s seven-fold, and Senegal’s eleven-fold! These numbers are indicative of the extent of dualism that marks poor economies. Taking developing countries as a whole, as much as a fifth of the productivity gap that separates them from the advanced

Note: Economy-wide labor productivity shown on the horizontal axis. Ratio of agricultural productivity to non-agricultural productivity (in percent) shown on vertical axis. Data for India, France, and Peru.

Figure 6. Relationship between economy-wide labor productivity and ratio of agricultural to non-agricultural productivity in India, France, and Peru.

countries would be eliminated by the kind of reallocation considered here.

Traditional dual-economy models emphasize the productivity gaps between the agricultural (rural) and non-agricultural (urban) parts of the economy. Indeed, the summary statistics in Table 1 show that agriculture is typically the lowest-productivity activity in the poorest economies. Yet another interesting stylized fact of the development process revealed by our data is that the productivity gap between the agricultural and non-agricultural sectors behaves non-monotonically during economic growth. The gap first increases and then falls, so that the ratio of agricultural to non-agricultural productivity exhibits a U-shaped pattern as the economy develops.

This is shown in Figure 5, where the productivity ratio between agriculture and non-agriculture (i.e., the rest of the economy) is graphed against the (log) of average labor productivity for our full panel of observations. A quadratic curve fits the data very well, and both terms of the equation are statistically highly significant. The fitted quadratic indicates that the turning point comes at an economy-wide productivity level of around \$9,000 ( $=\exp(9.1)$ ) per worker. This corresponds to a development level somewhere between that of India and China in 2005.

We can observe this U-shaped relationship also over time within countries, as is shown in Figure 6 which collates the time-series observations for three countries at different stages of development (India, Peru, and France). India, which is the poorest of the three countries, is on the downward sloping part of the curve. As its economy has grown, the gap between agricultural and non-agricultural productivity has increased (and the ratio of agricultural to non-agricultural productivity has fallen). France, a wealthy country, has seen the opposite pattern. As income has grown, there has been greater convergence in the productivity levels of the two types of sectors. Finally, Peru represents an intermediate case, having spent most of its recent history around the minimum-point at the bottom of the U-curve.

A basic economic logic lies behind the U-curve. A very poor country has few modern industries in the non-agricultural parts of the economy. So even though agricultural productivity is very low, there is not a large gap yet with the rest of the economy. Economic growth typically happens with investments in the modern, urban parts of the economy. As

these sectors expand, a wider gap begins to open between the traditional and modern sectors. The economy becomes more “dual.”<sup>6</sup> At the same time, labor begins to move from traditional agriculture to the modern parts of the economy, and this acts as a countervailing force. Past a certain point, this second force becomes the dominant one, and productivity levels begin to converge within the economy. This story highlights the two key dynamics in the process of structural transformation: the rise of new industries (i.e., economic diversification) and the movement of resources from traditional industries to these newer ones. Without the first, there is little that propels the economy forward. Without the second, productivity gains do not diffuse in the rest of the economy.

We end this section by relating our stylized facts to some other recent strands of the development literature that have focused on productivity gaps and misallocation of resources. There is a growing literature on productive heterogeneity within industries. Most industries in the developing world are a collection of smaller, typically informal firms that operate at low levels of productivity along with larger, highly productive firms that are better organized and use more advanced technologies. Various studies by the McKinsey Global Institute have documented in detail the duality within industries. For example, MGI’s analysis of a number of Turkish industries finds that on average the modern segment of firms is almost three times as productive as the traditional segment (MGI 2003, see Figure 7). Bartelsman, Haltiwanger, and Scarpetta (2006) and Hsieh and Klenow (2009) have focused on the dispersion in total factor productivity across plants, the former for a range of advanced and semi-industrial economies and the latter for China and India. Hsieh and Klenow’s (2009) findings indicate that between a third and a half of the gap in these countries’ manufacturing TFP vis-à-vis the United States would be closed if the “excess” dispersion in plant productivity was removed. There is also a substantial empirical literature, mentioned in the introduction, which underscores the allocative benefits of trade liberalization within manufacturing: as manufacturing firms are exposed to import competition, the least productive among them lose market share or shut down, raising the average productivity of those that remain.

Figure 7. Dual economy, Turkey. Source: McKinsey Global Institute (2003).

There is an obvious parallel between these studies and ours. Our data are too broad-brush to capture the finer details of misallocation within individual sectors and across plants and firms. But a compensating factor is that we may be able to track the general-equilibrium effects of re-allocation—something that analyses that remain limited to manufacturing cannot do. Improvements in manufacturing productivity that come at the expense of greater inter-sectoral misallocation—say because employment shifts from manufacturing to informality—need not be a good bargain. In addition, we are able to make comparisons among a larger sample of developing countries. So this paper should be viewed as a complement to the plant- or firm-level studies.

### 3. PATTERNS OF STRUCTURAL CHANGE AND PRODUCTIVITY GROWTH

We now describe the pace and nature of structural change in developing economies over the period 1990–2005. We focus on this period for two reasons. First, this is the most recent period, and one where globalization has exerted a significant impact on all developing nations. It will be interesting to see how different countries have handled the stresses and opportunities of advanced globalization. And second, this is the period for which we have the largest sample of developing countries.

We will demonstrate that there are large differences in patterns of structural change across countries and regions and that these account for the bulk of the differential performance between successful and unsuccessful countries. In particular, while Asian countries have tended to experience productivity-enhancing structural change, both Latin America and Africa have experienced productivity-reducing structural change. In the next section we will turn to an analysis of the determinants of structural change. In particular, we are

interested in understanding why some countries have the right kind of structural change while others have the wrong kind.

#### (a) Defining the contribution of structural change

Labor productivity growth in an economy can be achieved in one of two ways. First, productivity can grow *within* economic sectors through capital accumulation, technological change, or reduction of misallocation across plants. Second, labor can move *across* sectors, from low-productivity sectors to high-productivity sectors, increasing overall labor productivity in the economy. This can be expressed using the following decomposition:

$$\Delta Y_t = \sum_{i=n} \theta_{i,t-k} \Delta y_{i,t} + \sum_{i=n} y_{i,t} \Delta \theta_{i,t}, \tag{1}$$

where  $Y_t$  and  $y_{i,t}$  refer to economy-wide and sectoral labor productivity levels, respectively, and  $\theta_{i,t}$  is the share of employment in sector  $i$ . The  $\Delta$  operator denotes the change

Figure 8. Productivity decomposition for Latin America, 1950–2005.

in productivity or employment shares between  $t - k$  and  $t$ . The first term in the decomposition is the weighted sum of productivity growth within individual sectors, where the weights are the employment share of each sector at the beginning of the time period. We will call this the “within” component of productivity growth. The second term captures the productivity effect of labor re-allocations across different sectors. It is essentially the inner product of productivity levels (at the end of the time period) with the change in employment shares across sectors. We will call this second term the “structural change” term. When changes in employment shares are positively correlated with productivity levels, this term will be positive, and structural change will increase economy-wide productivity growth.

The decomposition above clarifies how partial analyses of productivity performance within individual sectors (e.g., manufacturing) can be misleading when there are large differences in labor productivities ( $y_{i,t}$ ) across economic activities. In particular, a high rate of productivity growth within an industry can have quite ambiguous implications for overall economic performance if the industry’s share of employment shrinks rather than expands. If the displaced labor ends up in activities with lower productivity, economy-wide growth will suffer and may even turn negative.

#### (b) Structural change in Latin America: 1950–2005

Before we present our own results, we illustrate this possibility with a recent finding on Latin America. When the Inter-American Development Bank recently analyzed the pattern of productivity change in the region since 1950, using the same Timmer and de Vries (2007, 2009) dataset and a very similar decomposition, it uncovered a striking result, shown in Figure 8. During 1950–75, Latin America experienced rapid (labor) productivity growth of almost 4% per annum, roughly half of which was accounted for by structural change. Then the region went into a debt crisis and experienced a “lost decade,” with productivity growth in the negative territory during 1975–90. Latin America returned to growth after 1990, but productivity growth never regained the levels seen before 1975. This is due entirely to the fact that the contribution of structural change has now turned *negative*. The “within” component of productivity growth is virtually identical in the two periods 1950–1975 and 1990–2005 (at 1.8% per annum). But the structural change component went from 2% during 1950–1975 to  $-0.2\%$  in 1990–2005, an astounding reversal in the course of a few decades.

This is all the more surprising in light of the commonly accepted view that Latin America’s policies and institutions improved significantly as a result of the reforms of the late 1980s and early 1990s. Argentina, Brazil, Mexico, Chile, Colombia, and most of the other economies got rid of high inflation, brought fiscal deficits under control, turned over monetary policy to independent central banks, eliminated financial repression, opened up their economies to international trade and capital flows, privatized state enterprises, reduced red tape and most subsidies, and gave markets freer rein in general. Those countries which had become dictatorships during the 1970s experienced democratic transitions, while others significantly improved governance as well. Compared to the macro-economic populism and protectionist, import-substitution policies that had prevailed until the end of the 1970s, this new economic environment was expected to yield significantly enhanced productivity performance.

The sheer scale of the contribution of structural change to this reversal of fortune has been masked by microeconomic

studies that record significant productivity gains for individual plants or industries, and further, find these gains to be strongly related to post-1990 policy reforms. In particular, study after study has shown that the intensified competition brought about by trade liberalization has forced manufacturing industries to become more productive (see for example Cavalcanti Ferreira & Rossi, 2003; Eslava, Haltiwanger, Kugler, & Kugler, 2009; Fernandes, 2007; Paus, Reinhardt, & Robinson, 2003; Pavcnik, 2000). A key mechanism that these studies document is what’s called “industry rationalization:” the least productive firms exit the industry, and remaining firms shed “excess labor.”

The question left unanswered is what happens to the workers that are thereby displaced. In economies which do not exhibit large inter-sectoral productivity gaps, labor displacement would not have important implications for economy-wide productivity. Clearly, this is not the case in Latin America. The evidence in Figure 8 suggests instead that displaced workers may have ended up in *less* productive activities. In other words, rationalization of manufacturing industries may have come at the expense of inducing growth-reducing structural change.

An additional point that needs making is that these calculations (as well as the ones we report below) do not account for unemployment. For a worker, unemployment is the least productive status of all. In most Latin American countries unemployment has trended upward since the early 1990s, rising by several percentage points of the labor force in Argentina, Brazil, and Colombia. Were we to include the displacement of workers into unemployment, the magnitude of the productivity-reducing structural change experienced by the region would look even more striking.<sup>7</sup>

Figure 8 provides an interesting new insight on what has held Latin American productivity growth back in recent years, despite apparent technological progress in many of the advanced sectors of the region’s economies. But it also raises a number of questions. In particular, was this experience a general one across all developing countries, and what explains it? If there are significant differences across countries in this respect, what are the drivers of these differences?

#### (c) Patterns of structural change by region

We present our central findings on patterns of structural change in Figure 9. Simple averages are presented for the 1990–2005 period for four groups of countries: Latin America, Sub-Saharan Africa, Asia, and high-income countries.<sup>8</sup>

Figure 9. Decomposition of productivity growth by country group, 1990–2005.

Table 3. *Decomposition of productivity growth, 1990–2005 (unweighted averages)*

	Labor Productivity	Component due to:	
	Growth (%)	“Within” (%)	“Structural” (%)
LAC	1.35	2.24	−0.88
AFRICA	0.86	2.13	−1.27
ASIA	3.87	3.31	0.57
HI	1.46	1.54	−0.09

We note first that structural change has made very little contribution (positive or negative) to the overall growth in labor productivity in the high-income countries in our sample. This is as expected, since we have already noted the disappearance of inter-sectoral productivity gaps during the course of development. Even though many of these advanced economies have experienced significant structural change during this period, with labor moving predominantly from manufacturing to service industries, this (on its own) has made little difference to productivity overall. What determines economy-wide performance in these economies is, by and large, how productivity fares in each individual sector.

The developing countries exhibit a very different picture. Structural change has played an important role in all three regions. But most striking of all is the differences among the regions. In both Latin America and Africa, structural change has made a sizable negative contribution to overall growth, while Asia is the only region where the contribution of structural change is positive. (The results for Latin America do not match exactly those in Figure 8 because we have applied a somewhat different methodology when computing the decomposition than that used by Pages, 2010.<sup>9</sup>) We note again that these computations do not take into account unemployment. Latin America (certainly) and Africa (possibly) would look considerably worse if we accounted for the rise of unemployment in these regions.

Hence, the curious pattern of growth-reducing structural change that we observed above for Latin America is repeated in the case of Africa. This only deepens the puzzle as Africa is substantially poorer than Latin America. If there is one region

where we would have expected the flow of labor from traditional to modern parts of the economy to be an important driver of growth, a la dual-economy models, that surely is Africa. The disappointment is all the greater in light of all of the reforms that African countries have undergone since the late 1980s. Yet labor seems to have moved from high- to low-productivity activities on average, reducing Africa’s growth by 1.3 percentage points per annum on average (Table 3). Since Asia has experienced growth-enhancing structural change during the same period, it is difficult to ascribe Africa’s and Latin America’s performance solely to globalization or other external determinants. Clearly, country-specific forces have been at work as well.

Differential patterns of structural change in fact account for the bulk of the difference in regional growth rates. This can be seen by checking the respective contributions of the “within” and “structural change” components to the differences in productivity growth in the three regions. Asia’s labor productivity growth in 1990–2005 exceeded Africa’s by 3 percentage points per annum and Latin America’s by 2.5 percentage points. Of this difference, the structural change term accounts for 1.84 points (61%) in Africa and 1.45 points (58%) in Latin America. We saw above that the decline in the contribution of structural change was a key factor behind the deterioration of Latin American productivity growth since the 1960s. We now see that the same factor accounts for the lion’s share of Latin America’s (as well as Africa’s) under-performance relative to Asia.

In other words, where Asia has outshone the other two regions is not so much in productivity growth within individual sectors, where performance has been broadly similar, but in

Figure 10. *Decomposition of productivity growth by country group, 1990–2005 (weighted averages).*

ensuring that the broad pattern of structural change contributes to, rather than detracts from, overall economic growth. As Table 4 shows, some mineral-exporting African countries such as Zambia and Nigeria have in fact experienced very high productivity growth at the level of individual sectors, as have many Latin American countries. But when individual countries are ranked by the magnitude of the structural change term, it is Asian countries that dominate the top of the list.

The regional averages we have discussed so far are un-weighted averages across countries that do not take into account differences in country size. When we compute a regional average that sums up value added and employment in the same sector across countries, giving more weight to larger countries, we obtain the results shown in Figure 10. The main difference now is that we get a much larger “within” component for Asia, an artifact of the predominance of China in the weighted sample. Also, the negative structural change component turns very slightly positive in Latin America, indicating that labor flows in the larger Latin American countries have not gone as much in the wrong direction as they have in the smaller ones. Africa still has a large and negative structural change term. Asia once more greatly outdoes the other two

developing regions in terms of the contribution of structural change to overall growth.

(d) *More details on individual countries and sectors*

The presence of growth-reducing structural change on such a scale is a surprising phenomenon that calls for further scrutiny. We can gain further insight into our results by looking at the sectoral details for specific countries. We note that growth-reducing structural change indicates that the direction of labor flows is negatively correlated with (end-of-period) labor productivity in individual sectors. So for selected countries we plot the (end-of-period) relative productivity of sectors ( $y_{i,t}/Y_t$ ) against the change in their employment share ( $\Delta\theta_{i,t}$ ) during 1990–2005. The relative size of each sector (measured by employment) is indicated by the circles around each sector’s label in the scatter plots. The next six figures (Figures 11–16) show sectoral detail for two countries each from Latin America, Africa, and Asia.

Argentina shows a particularly clear-cut case of growth-reducing structural change (Figure 11). The sector with the largest relative loss in employment is manufacturing, which also happens to be the largest sector among those with above-average productivity. Most of this reduction in manufacturing employment took place during the 1990s, under the Argentine experiment with hyper-openness. Even though the decline in manufacturing was halted and partially reversed during the recovery from the financial crisis of 2001–2002, this was not enough to change the overall picture for the period 1990–2005. By contrast, the sector experiencing the largest employment gain is community, personal, and government services, which has a high level of informality and is among the least productive. Hence the sharply negative slope of the Argentine scatter plot.

Brazil shows a somewhat more mixed picture (Figure 12). The collapse in manufacturing employment was not as drastic as in Argentina (relatively speaking), and it was somewhat counterbalanced by the even larger contraction in agriculture, a significantly below-average productivity sector. On the other hand, the most rapidly expanding sectors were again relatively unproductive non-tradable sectors such as personal and community services and wholesale and retail trade. On balance,

\*Note: Size of circle represents employment share in 1990

Figure 11. *Correlation between sectoral productivity and change in employment shares in Argentina (1990–2005).*

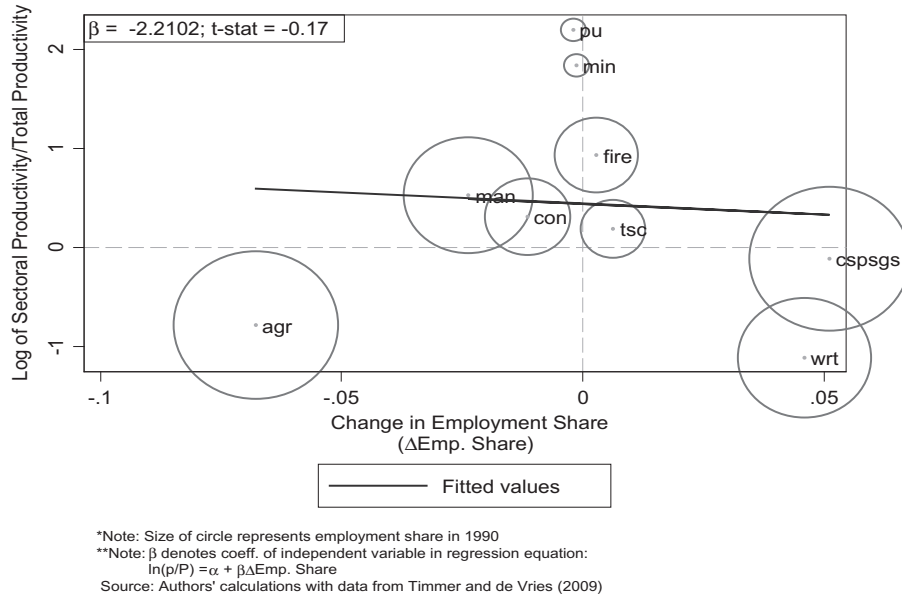

Figure 12. Correlation between sectoral productivity and change in employment shares in Brazil (1990–2005).

Figure 13. Correlation between sectoral productivity and change in employment shares in Nigeria (1990–2005).

the Brazilian slope is slightly negative, indicating a small growth-reducing role for structural change.

The African cases of Nigeria and Zambia show negative structural change for somewhat different reasons (Figures 13 and 14). In both countries, the employment share of agriculture has increased significantly (alongside with community and government services in Nigeria). By contrast, manufacturing and relatively productive tradable services have experienced a contraction—a remarkable anomaly for countries at such low levels of development, in which these sectors are quite small to begin with. The expansion of agricultural employment in Zambia is particularly large—about 5 percentage points of total employment during 1990–2005.<sup>10</sup> These figures indicate a veritable exodus from the rest of the economy back to agriculture, where labor productivity is roughly half of what it is elsewhere. Thurlow and Wobst (2005, pp. 24–25) describe how the decline of formal employment in Zambian manufacturing during the

1990s as a result of import liberalization led to many low-skilled workers ending up in agriculture.

Africa exhibits a lot of heterogeneity, however, and the expansion of agricultural employment that we see in Nigeria and Zambia is not a common phenomenon across the continent. In general the sector with the largest relative loss in employment is wholesale and retail trade where productivity is higher (in Africa) than the economy-wide average. The expansion of employment in manufacturing has been meager, at around one quarter of 1% over the fifteen year period. The sector experiencing the largest employment gain tends to be community, personal, and government services, which has a high level of informality and is the least productive.

Ghana, Ethiopia, and Malawi are three countries that have experienced growth-enhancing structural change. In all three cases, the share of employment in the agricultural sector has declined while the share of employment in the manufacturing

Figure 14. Correlation between sectoral productivity and change in employment shares in Zambia (1990–2005).

sector has increased. However, labor productivity in manufacturing remains notably low in both Ghana and Ethiopia.

Compare the African cases now to India, which has experienced significant growth-enhancing structural change since 1990. As Figure 15 shows, labor has moved predominantly from very low-productivity agriculture to modern sectors of the economy, including notably manufacturing. India is one of the poorest countries in our sample, so its experience need not be representative. But another Asian country, Thailand, shows very much the same pattern (Figure 16). In fact, the magnitude of growth-enhancing structural change in Thailand has been phenomenal, with agriculture’s employment share declining by some 20 percentage points and manufacturing experiencing significant gains.

Not all Asian countries exhibit this kind of pattern. South Korea and Singapore, in particular, look more like Latin American countries in that high-productivity manufacturing sectors have shrunk in favor of some relatively lower-

productivity service activities. But in both of these cases, very rapid “within” productivity growth has more than offset the negative contribution from structural change. That has not happened in Latin America. Moreover, a contraction in the share of the labor force in manufacturing is not always a bad thing. For example, in the case of Hong Kong, the share of the labor force in manufacturing fell by more than 20%. But because productivity in manufacturing is lower than productivity in most other sectors, this shift has produced growth-enhancing structural change.

(e) Decomposing the results: 1990–99 and after 2000

There are a number of reasons to believe that structural change might have been delayed in much of Africa. And it is only relatively recently that much of Africa has begun to grow rapidly. Part of this has to do with the rise in commodity prices that began in the early 2000s. But it may also be that

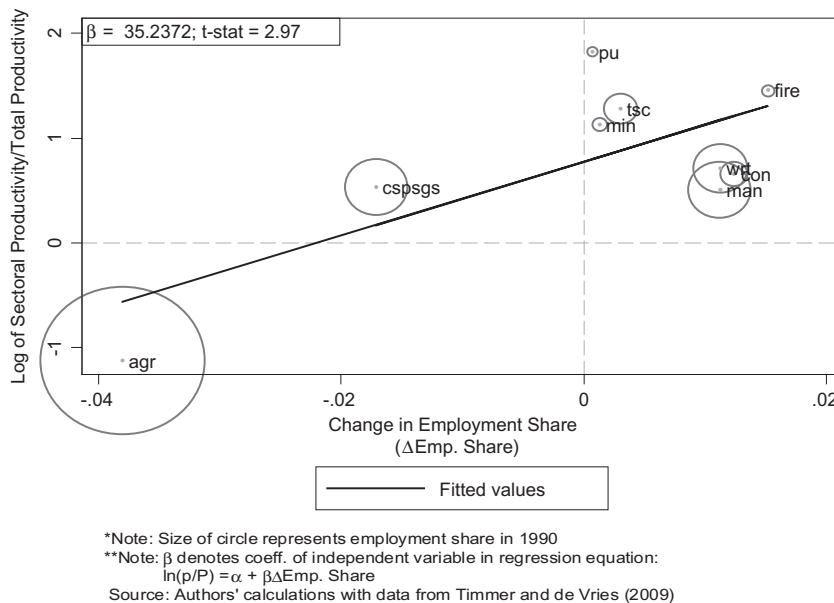

Figure 15. Correlation between sectoral productivity and change in employment shares in India (1990–2005).

Figure 16. Correlation between sectoral productivity and change in employment shares in Thailand (1990–2005).

Africa is starting to reap the benefits of economic reforms and improved governance. To explore these possibilities, we turn our attention to an investigation of structural change for the periods 1990–99 and then after 2000.<sup>11</sup> The latter period is particularly relevant for Africa because this is the period over which Africa experienced its strongest growth in three decades. The key question is whether growth in this period was accompanied by structural change.

Simple averages and employment weighted averages are presented for the periods 1990–99 and after 2000 by region in Figures 17a–17d. The most striking result that jumps out from these figures is Africa’s remarkable turnaround. During 1990–99, structural change was a drag on economy-wide productivity in Africa: in the unweighted sample overall growth in labor productivity was negative and largely a result of structural change. But post-2000, structural change contributed around 1.4 percentage points to labor productivity growth in the weighted sample and around 0.4 percentage points in the unweighted sample. Moreover, overall labor productivity growth in Africa was second only to Asia where structural change continued to play an important positive role. The results for Latin America and the High Income Countries in the sample are qualitatively similar across periods.

To understand the nature of the structural change in Africa after 2000, we first consider the cases of Nigeria and Zambia (where data extend beyond 2005). In Section D, we noted that for the period 1990–2005, both of these countries exhibited

Figure 17b. Decomposition of productivity growth by country group, 1990–1999 (weighted).

Figure 17a. Decomposition of productivity growth by country group, 1990–1999 (unweighted).

Figure 17c. Decomposition of productivity growth by country group, after 2000 (unweighted).

Figure 17d. *Decomposition of productivity growth by country group, after 2000 (weighted).*

growth reducing structural change. Figures 18a and 18b illustrate the turnaround in both of these countries. In both cases, we see an expansion of the manufacturing sector after 2000 and a contraction in agriculture and services. The changes in employment shares in Nigeria and Zambia are small compared to the expansion of the manufacturing sectors in many Asian countries. Nevertheless, the figures do indicate that the structural change is not simply driven by an expansion in the services sector.

Looking at the post-2000 period, of the nine countries in our Africa sample, Ethiopia and Malawi exhibit patterns similar to Nigeria and Zambia. In two others—Kenya and Senegal—structural change was primarily driven by an expansion in the services sector but Senegal’s expansion in services is qualitatively different in that average productivity in the services sector in Senegal is quite high. The three middle income countries in the sample—Ghana, Mauritius, and South Africa—appear to be on quite different paths. In Mauritius, the share of employment in manufacturing fell by more than 5% but this was offset by a similar expansion in services where labor productivity was nearly double that in manufacturing. By contrast, the share of employment in Ghana’s and South Africa’s manufacturing sectors barely changed while labor

moved from agriculture into the service sector where productivity was roughly equal to that in agriculture (for Ghana) and manufacturing (for South Africa).

Summarizing, in around half of the countries in our Africa sample, the recent growth episode (i.e., after 2000) has been accompanied by small expansions in the manufacturing sector. The magnitude of the changes is not enough to rapidly transform these economies. Nevertheless, they are a step in the right direction and they indicate that Africa’s recent growth could be sustainable if things continue to move in the right direction.

4. WHAT EXPLAINS THESE PATTERNS OF STRUCTURAL CHANGE?

All developing countries in our sample have become more “globalized” during the time period under consideration. They have phased out remaining quantitative restrictions on imports, slashed tariffs, encouraged direct foreign investment and exports, and, in many cases, opened up to cross-border financial flows. So it is natural to think that globalization has played an important behind-the-scenes role in driving the patterns of structural change we have documented above.

However, it is also clear that this role cannot have been a direct, straightforward one. For one thing, what stands out in the findings described previously is the wide range of outcomes: some countries (mostly in Asia) have continued to experience rapid, productivity-enhancing structural change, while others (mainly in Africa and Latin America) have begun to experience productivity-reducing structural change. A common external environment cannot explain such large differences. Second, as important as agriculture, mining, and manufacturing are, a large part—perhaps a majority—of jobs are still provided by non-tradable service industries. So whatever contribution globalization has made, it must depend heavily on local circumstances, choices made by domestic policy makers, and domestic growth strategies.

We have noted above the costs that premature de-industrialization have on economy-wide productivity. Import competition has caused many industries to contract and release labor to less productive activities, such as agriculture and

\*Note: Size of circle represents employment share in 1999  
 \*\*Note: β denotes coeff. of independent variable in regression equation:

 Source: Authors’ calculations with data from Nigeria’s National Bureau of Statistics, ILO’s LABORSTA and Adeyinka, Salau and Vollrath (2012)

Figure 18a. *Correlation between sectoral productivity and change in employment shares in Nigeria (1999–2009).*

Figure 18b. Correlation between sectoral productivity and change in employment shares in Zambia (2000–2006).

informality. One important difference among countries may be the degree to which they are able to manage such downsides. A notable feature of Asian-style globalization is that it has had a two-track nature: many import-competing activities have continued to receive support while new, export-oriented activities were spawned. For example, until the mid-1990s, China had liberalized its trade regime at the margin only. Firms in special economic zones (SEZs) operated under free-trade rules, while domestic firms still operated behind high trade barriers. State enterprises still continue to receive substantial support. In an earlier period, South Korea and Taiwan pushed their firms onto world markets by subsidizing them heavily, and delayed import liberalization until domestic firms could stand on their feet. Strategies of this sort have the advantage, from the current perspective, of ensuring that labor remains employed in firms that might otherwise get decimated by import competition. Such firms may not be the most efficient in the economy, but they often provide jobs at productivity levels that exceed their employees' next-best alternative (i.e., informality or agriculture).

A related issue concerns the real exchange rate. Countries in Latin America and Africa have typically liberalized in the context of overvalued currencies—driven either by disinflationary monetary policies or by large foreign aid inflows. Overvaluation squeezes tradable industries further, damaging especially the more modern ones in manufacturing that operate at tight profit margins. Asian countries, by contrast, have often targeted competitive real exchange rates with the express purpose of promoting their tradable industries. Below, we will provide some empirical evidence on the role played by the real exchange rate in promoting desirable structural change.

Globalization promotes specialization according to comparative advantage. Here there is another potentially important difference among countries. Some countries—many in Latin America and Africa—are well-endowed with natural resources and primary products. In these economies, opening up to the world economy reduces incentives to diversify toward modern manufactures and reinforces traditional specialization patterns. As we have seen, some primary sectors such as minerals do operate at very high levels of labor productivity. The problem with such activities, however, is that they have a very limited capacity to generate substantial employment. So in

economies with a comparative advantage in natural resources, we expect the positive contribution of structural change associated with participation in international markets to be limited. Asian countries, most of which are well endowed with labor but not natural resources, have a natural advantage here. The regression results to be presented below bear this intuition out.

The rate at which structural change in the direction of modern activities takes place can also be influenced by ease of entry and exit into industry and by the flexibility of labor markets. [Ciccone and Papaioannou \(2008\)](#) show that intersectoral reallocation within manufacturing industries is slowed down by entry barriers. When employment conditions are perceived as “rigid,” say because of firing costs that are too high, firms are likely to respond to new opportunities by upgrading plant and equipment (capital deepening) rather than by hiring new workers. This slows down the transition of workers to modern economic activities. This hypothesis also receives some support from the data.

We now present the results of some exploratory regressions aimed at uncovering the main determinants of differences across countries in the contribution of structural change ([Table 5](#)). We regress the structural-change term over the 1990–2005 period (the second term in Eqn. (1), annualized in percentage terms) on a number of plausible independent variables. We view these regressions as a first pass through the data, rather than a full-blown causal analysis.

We begin by examining the role of initial structural gaps. Clearly, the wider those gaps, the larger the room for growth-enhancing structural change for standard dual-economy model reasons. We proxy these gaps by agriculture's employment share at the beginning of the period (1990). Somewhat surprisingly, even though this variable enters the regression with a positive coefficient, it falls far short of statistical significance (column 1). The implication is that domestic convergence, just like convergence with rich countries, is not an unconditional process. Starting out with a significant share of your labor force in agriculture may increase the potential for structural-change induced growth, but the mechanism is clearly not automatic.

Note that we have included regional dummies (in this and all other specifications), with Asia as the excluded category.

Table 5. *Determinants of the magnitude of the structural change term*

Dependent variable: structural change term					
	(1)	(2)	(3)	(4)	(5)
Agricultural share in employment	0.013 (0.98)	0.027 (2.26)**	0.016 (1.48)	0.023 (2.45)**

Robust *t*-statistics in parenthesis.

\*Significant at 1% level.

\*\*Significant at 5% level.

\*\*\*Significant at 10% level.

The statistically significant coefficients on Latin America and Africa (both negative) indicate that the regional differences we have discussed previously are also meaningful in a statistical sense.

We next introduce the share of a country's exports that is accounted for by raw materials, as an indicator of comparative advantage. This indicator enters with a negative coefficient, and is highly significant (column 2). There is a very strong and negative association between a country's reliance on primary products and the rate at which structural change contributes to growth. Countries that specialize in primary products are at a distinct disadvantage.

We note two additional points about column (2). First, agriculture's share in employment now turns statistically significant. This indicates the presence of conditional convergence: conditional on not having a strong comparative advantage in primary products, starting out with a large countryside of surplus workers does help. Second, once the comparative advantage indicator is entered, the coefficients on regional dummies are slashed and they are no longer statistically significant. In other words, comparative advantage and the initial agricultural share can jointly fully explain the large differences in average performance across regions. Countries that do well are those that start out with a lot of workers in agriculture but do not have a strong comparative advantage in primary products. That most Asian countries fit this characterization explains the Asian difference we have highlighted above.

For trade/currency practices, we use a measure of the undervaluation of a country's currency, based on a comparison of price levels across countries (after adjusting for the Balassa-Samuelson effect; see [Rodrik, 2008](#)). For labor markets, we use the employment rigidity index from the World Bank's World Development Indicators data base. The results in columns (3)–(5) indicate that both of these indicators enter the

regression with the expected sign and are statistically significant. Undervaluation promotes growth-enhancing structural change, while employment rigidity inhibits it.

We have tried a range of other specifications and additional regressors, including income levels, demographic indicators, institutional quality, and tariff levels. But none of these variables have turned out to be consistently significant.

## 5. CONCLUDING COMMENTS

Large gaps in labor productivity between the traditional and modern parts of the economy are a fundamental reality of developing societies. In this paper, we have documented these gaps, and emphasized that labor flows from low-productivity activities to high-productivity activities are a key driver of development.

Our results show that since 1990 structural change has been growth reducing in both Africa and Latin America, with the most striking changes taking place in Latin America. The bulk of the difference between these countries' productivity performance and that of Asia is accounted for by differences in the pattern of structural change—with labor moving from low- to high-productivity sectors in Asia, but in the opposite direction in Latin America and Africa. Our results also show that things seem to be turning around in Africa: after 2000, structural change contributed positively to Africa's overall productivity growth.

For Africa, these results are encouraging. But at least for now, most countries in Africa are still playing catch up to where they were decades ago. However, the very low levels of productivity and industrialization across most of the continent indicate an enormous potential for growth through structural change. To achieve this potential, African governments will need to support activities in which large numbers of

unskilled workers can be relatively more productive than in subsistence agriculture.

Several recent trends in the global economy provide Africa with unprecedented opportunities. Increasing agricultural productivity in Africa and rising global food and commodity prices coupled with stable macro and political trends have made foreign and local entrepreneurs more willing to invest in agribusiness in Africa.<sup>12</sup> Rising wages in China make Africa a more attractive destination for labor intensive manufacturing. The global search for natural resources has given African governments more bargaining power and financial resources. And the spread of democracy in Africa makes it more likely that these resources will be used to foster positive structural change. It remains to be seen whether governments in Africa can take advantage of these opportunities to achieve the kind of structural change that leads to broad based sustainable growth.

In some ways, the challenge for countries in Latin America is more complicated and more similar to the challenges faced by high income countries. Countries in Latin America are richer and far more industrialized than countries in Africa. Undoubtedly the contraction in the manufacturing sector across Latin America and in most high income countries is partly a result of China's ascendancy in world manufacturing.<sup>13</sup>

In these countries, firms that were exposed to foreign competition had no choice but to either become more productive or shut down. As trade barriers have come down, industries have rationalized, upgraded, and become more efficient. But an economy's overall productivity depends not only on what is happening within industries, but also on the reallocation of resources across sectors. This is where globalization has produced a highly uneven result.

Nevertheless, there are some commonalities. Our empirical work shows that countries with a comparative advantage in natural resources run the risk of stunting their process of structural transformation. The risks are aggravated by policies that allow the currency to become overvalued and place large costs on firms when they hire or fire workers. In this respect, Nigeria and Venezuela are equally vulnerable.

Structural change, like economic growth itself, is not an automatic process. It needs a nudge in the appropriate direction, especially when a country has a strong comparative advantage in natural resources. Globalization does not alter this underlying reality. But it does increase the costs of getting the policies wrong, just as it increases the benefits of getting them right.<sup>14</sup>

## NOTES

1. See for example [Esclava et al. \(2009\)](#), [Fernandes \(2007\)](#), [McMillan, Rodrik, and Welch \(2003\)](#) and [Pavcnik \(2000\)](#).

2. Based on weighted averages of labor productivity growth. This contribution is still significant (although slightly smaller) for unweighted averages, accounting for about 20% of overall growth in our Africa subsample.

3. The original GGDC sample also includes West Germany, but we dropped it from our sample due to the truncation of the data after 1991. The latest update available for each country was used. Data for Latin American and Asian countries came from the June 2007 update, while data for the European countries and the United States came from the October 2008 update.

4. For a detailed explanation of the protocols followed to compile the GGDC 10-Sector Database, the reader is referred to the "Sources and Methods" section of the database's web page: [http://www.ggdc.net/databases/10\\_sector.htm](http://www.ggdc.net/databases/10_sector.htm).

5. The inter-sectoral distribution of employment for high-income countries is calculated as the simple average of each sector's employment share across the high-income sample.

6. See [Kuznets \(1995\)](#) for an argument along these lines. However, Kuznets conjectured that the gap between agriculture and industry would keep increasing, rather than close down as we see here.

7. We have undertaken some calculations along these lines, including "unemployment" as an additional sector in the decomposition. Preliminary calculations indicate that the rise in unemployment during 1990–2005 worsens the structural change term by an additional 0.2 percentage points. We hope to report results on this in future work.

8. Even though Turkey is in our dataset, this country has not been included in this and the next figure because it is the only Middle Eastern country in our sample.

9. We fixed some data discrepancies and used a 9-sector disaggregation to compute the decomposition rather than IDB's 3-sector disaggregation. See the data appendix for more details.

10. [McMillan and Rodrik \(2011\)](#) report that this change was closer to 20%. In this update, we have revised employment data for Zambia. The differences are due to an apparent inconsistency in sectoral employment estimates from the 1990 Population and Housing Census. Trends in sectoral employment shares and sectoral employment estimates from nationally-representative household surveys from 1990 on show that the 1990 census underestimates employment levels in agriculture and overestimates its share in total employment. For this reason, we revised our 1990 sectoral employment estimates to be consistent with these trends. We thank James Thurlow for informing us of this inconsistency in the Zambian 1990 census data.

11. For non-African economies the post-2000 period covers up to 2005. For African countries, we used the most recent year for which we had data. For the latter, the post-2000 period covers up to 2005 for Ethiopia, Kenya, Malawi, and Senegal; up to 2006 for Zambia, 2007 for South Africa and Mauritius, 2009 for Nigeria, and 2010 for Ghana.

12. See [Radelet \(2010\)](#).

13. See for example [Autor, Dorn, and Hanson \(2012\)](#) and [Ebenstein, McMillan, Zhao, and Zhang \(2012\)](#).

14. This is not the place to get into an extended discussion on policies that promote economic diversification. See [Cimoli, Dosi, and Stiglitz \(2009\)](#) and [Rodrik \(2007\)](#), chap. 4.

15. (1) Agriculture; (2) Mining and Quarrying; (3) Manufacturing; (4) Public Utilities; (5) Construction; (6) Wholesale and Retail Trade, Hotels and Restaurants; (7) Transport, Storage and Communication; and (8) Finance, Insurance and Business Services. Finally, Community, Social, and Personal services and Producers of Government Services were

aggregated into a single sector (9). We decided to aggregate these sectors since data on Producers of Government Services are included in the Community, Social, and Personal services sector for a number of Latin American countries as well as African economies in national sources. In addition, a series for the total of all sectors is also included.

16. Available at [http://www.ggdc.net/databases/10\\_sector.htm](http://www.ggdc.net/databases/10_sector.htm). The latest update available for each country was used. Data for Latin American and Asian countries came from the June 2007 update, while data for the European countries and the US came from the October 2008 update.

17. While Timmer and de Vries (2009) only include data for developing Asian and Latin American countries, the online version of the 10-Sector Database also included some developed countries. We dropped West Germany from the sample due to the truncation of the data after 1991.

18. Agriculture; Mining; Manufacturing; Public Utilities; Construction; Retail and Wholesale Trade; Transport and Communication; Finance and Business Services; Community, Social, and Personal services; and Government Services.

19. They use sectoral value added levels from the latest available benchmark year and link these with series for previous benchmark years using sectoral value added growth rates calculated from the latter. For further details see Timmer and de Vries (2007).

20. Timmer and de Vries (2009) do note, however that while this was the general strategy they used to get sectoral employment levels for most countries, they had to use alternative sources (e.g., household surveys) in some cases.

21. We used STATA's *ipolate* command (along with its *epolate* option).

22. In the original 10-Sector Database, some inconsistencies were found for the value added in constant local currency units series for Brazil. Namely, the sum of the disaggregated sectors did not add up to the series for the aggregated values presented in the original dataset (the series under "Sectoral Sum"). For all other countries, the sum of the sectors' constant value added in local currency units did equal the value under "Sectoral Sum." So the fact that this was not the case for Brazil seemed anomalous. This was acknowledged by the 10-Sectoral Database manager in the

University of Groningen but the underlying cause remained unclear. This was corrected by substituting the "Sectoral Sum" series with the sum across sectors of the disaggregated value added in constant local currency units for each year.

23. We used PPP conversion factors from the PWT 6.3.

24. Note that Japan is included in the high-income sample, not Asia.

25. In cases where this was not available, data from the UN's System of National Accounts: Main Aggregates and Detailed Tables (which publish data from national sources) and the UN's National Accounts Main Aggregates online database were used.

26. This was our general approach but, in some cases, data availability forced us to complement census data with data on the sectoral distribution of employment from other sources such as informal sector surveys and household surveys.

27. We linked these series with the ones having 1998 as a benchmark year using yearly sectoral value added growth rates for the 1968–98 period published by Turkstat.

28. Due to data availability we were only able to calculate estimates of sectoral employment for our nine sectors of interest from 1990 to 2001. We compared our sectoral employment estimates with those published by the Asian Productivity Organization (APO) in its APO Productivity Database. Our sectoral employment estimates are identical to the ones calculated by the APO for all but the three sectors: utilities, wholesale and retail trade, and the community, social, personal, and government services sectors. Overall, these discrepancies were small. Moreover, while our sectoral employment estimates only cover the 1990–2001 period, the APO employment estimates go from 1978 to 2007. Given the close match between our estimates and those from the APO, and the longer time period covered by the APO data, we decided to use APO's sectoral employment estimates in order to maintain intertemporal consistency in the sectoral employment data for China.

29. Total GDP (in constant 2000 \$US) and total population in Sub-Saharan Africa in 2009.

variety of national and international sources (see Table 6). Similarly, we used data from several population censuses as well as labor and household surveys to get estimates of sectoral employment. Following Timmer and de Vries (2009), we define sectoral employment as all persons employed in a particular sector, regardless of their formality status or whether they were self-employed or family-workers. Moreover, we favor the use of population census data over other sources to gauge levels of employment by sector and complement these data with labor force surveys (LFS) or comprehensive household surveys.

### *The GGDC 10-Sector Database*

The Groningen Growth and Development Center (GGDC) 10-Sector Database<sup>16</sup> is an unbalanced panel of 28 countries: nine from Latin America, ten from Asia, eight from Europe and the United States.<sup>17</sup> It spans 55 years (1950–2005) and includes yearly data on employment and value added (in current and constant prices), disaggregated into 10 sectors.<sup>18</sup>

To get consistent data for sectoral value added, Timmer and de Vries (2009) use the most recent sectoral value added levels available from national accounts data published by national statistical offices or central banks. They link these series with sectoral value added series with different benchmark years to get consistent time series data on sectoral value added.<sup>19</sup> They reason that, in this way, growth rates of sectoral value added are preserved while the levels are estimated based on the latest available information and methods, making the resulting series intertemporally consistent. On the other hand, national accounts data are collected and aggregated from national sources using fairly similar methodologies and definitions between countries (ISIC rev. 2), ensuring that sectoral value added series remain consistent across countries.

While there has been a big effort from different international organizations and governments to gather and publish fairly standardized measures of value added that are intertemporally and internationally consistent; efforts to standardize measures of sectoral employment have yet to achieve the same level of consistency. Differences in the definitions of sectors between years, the scope of the surveys used to measure employment and, to a lesser extent, the definition of the different sectors in the economy are common in sectoral employment figures published by national governments and many international organizations. Labor force surveys (LFS) give employment estimates that use similar concepts and sectoral definitions across countries, but

## APPENDIX A. DATA DESCRIPTION

In this appendix we discuss the sources and methods we followed to create our dataset. We base our analysis on a panel of 38 countries with data on employment, value added (in 2000 PPP US dollars), and labor productivity (also in 2000 PPP US dollars) disaggregated into nine economic sectors,<sup>15</sup> starting in 1990 and ending in 2005. Our main source of data is the 10-Sector Productivity Database, by Timmer and de Vries (2009). We supplemented the 10-Sector Database with data for Turkey, China, and nine African countries: Ethiopia, Ghana, Kenya, Malawi, Mauritius, Nigeria, Senegal, South Africa, and Zambia.

In compiling this extended dataset, we followed Timmer and de Vries (2009) as closely as possible so that the resulting value added, employment and labor productivity data would be comparable to that of the 10-Sector Database. We gathered data on sectoral value added, aggregated into nine main sectors according to the definitions in the 2nd revision of the international standard industrial classification (ISIC, rev. 2), from national accounts data from a

sampling size and methods still differ between countries (Timmer & de Vries, 2009). For example, LFS from some countries only collect data from certain urban areas, leaving rural workers out of the sample. Another common source of sectoral employment data are business surveys. Timmer and de Vries (2009) note that one of the major shortcomings of this kind of survey is that they tend to exclude businesses below a certain size (e.g., below a certain number of employees). This tends to bias sectoral employment estimates against sectors where self-employed and/or informal workers are more prevalent (e.g., agriculture or retail trade).

Timmer and de Vries (2009) deal with the shortcomings of available data on sectoral employment by focusing on population censuses. They argue that the main reason behind their choice is that sectoral employment estimates from these sources cover all persons employed in each sector, regardless of their rural or urban status, size of establishment, job formality status, or whether they are employees, self-employed, or family-workers. On the other hand, an important shortcoming of these kind of data is the low frequency with which they are measured and published. For this reason, to arrive at yearly sectoral estimates Timmer and de Vries (2009) complement data on levels of employment by sector from population censuses with data on sectoral employment growth rates from available business surveys and LFS data.<sup>20</sup>

For a number of countries (especially in Latin America), the 10-Sector Database does not distinguish between value added or employment (or both) in the “Producers of Government Services” sector and the “Community, Social, and Personal Services” sector. Accordingly we were forced to increase the level of aggregation to nine sectors. In order to allow for international comparisons, we aggregated data on employment and value added for the “Producers of Government Services” and “Community, Social, and Personal Services” sectors into a single sector.

Given the unbalanced nature of the 10-Sector Dataset, we made small modifications to balance the panel. While the panel is balanced during 1990–2003, Bolivia, India, and Japan have missing data for one or several variables for 2004 and/or 2005. To balance the panel up to 2005, we extrapolated missing values for 2004 and 2005.<sup>21</sup> This performs a simple extrapolation of data using the slope between the two latest available observations (i.e., 2003 and 2004, if the missing value is for 2005), thus obtaining extrapolated values for the missing data points. While one needs to be careful with extrapolations for longer periods, given the short time span (2004 and 2005) and small number of gaps in the original data for this period, the risk of introducing biases to the results due to extrapolation was negligible. Thus, simple extrapolation seemed like a sensible choice to balance the panel. We performed consistency checks to each country’s data to ensure that our resulting dataset was internally consistent and consistent across time.<sup>22</sup>

Once we had a balanced panel, data on value added by country and sector were converted to constant 2000 PPP US dollars.<sup>23</sup> Labor productivity values for each country and sector were created by dividing each sector’s constant value added in 2000 PPP US dollars by its corresponding level of sectoral employment. The resulting database was a balanced panel for 27 countries, with sectoral and aggregate data on employment, value added (in constant 2000 PPP US dollars), and labor productivity (also in constant 2000 PPP US dollars), spanning the period 1990–2005 and disaggregated into nine sectors. Finally, these 27 countries were classified into three different regions: Latin America, Asia, and High Income.<sup>24</sup>

### *Supplementing the 10-Sector Database*

In supplementing the 10-Sector Database we were careful to follow Timmer and de Vries’ (2007, 2009) approach as closely as possible to ensure that the definitions and methods we used were comparable to the ones they used. We used data on value added by sector (classified according to the ISIC rev. 2) from national accounts data published by national statistics offices or central banks.<sup>25</sup> Similarly, we favored data from population census to get sectoral employment levels and the sectoral distribution of employment, while using LFS, business surveys, and/or comprehensive household survey to gauge sectoral employment growth trends between census years.<sup>26</sup>

Data on value added by sector for Turkey come from national accounts data from the Turkish Statistical Institute (TurkStat). The latest available benchmark year is 1998 and TurkStat publishes sectoral value added figures (in current and constant 1998 prices) with this benchmark year starting in 1998 and going all the way up to 2009. These series were linked with series on sectoral value added (in current and constant prices) with a different benchmark year (i.e., 1987) which yielded sectoral value added series going from 1968 to 2009.<sup>27</sup> This was done for sectoral value added in current and constant prices. Data on employment by sector come from sectoral employment estimates published by Turkstat. These estimates come from annual household LFS that are updated with data from the most recent population census. These surveys cover all persons employed regardless of their rural or urban status, formality status, and cover self-employed and family workers. Hence, they seem to be a good and reliable source of total employment by sector.

Chinese data were compiled from several China Statistical Yearbooks, published by the National Bureau of Statistics (NBS). The Statistical Yearbooks include data on value added (in current and constant prices) disaggregated into three main “industries”: primary, secondary, and tertiary. The NBS further decomposes the secondary industry series into construction and “industry” (i.e., all other non-construction activities in the secondary sector). The tertiary industry series includes data on services. In order to get disaggregated value added series for the other seven sectors of interest (i.e., sectors other than agriculture and construction) we had to disaggregate value added data for the secondary and tertiary sectors. We did this by calculating sectoral distributions of value added for the non-construction secondary industry and tertiary industry from different tables published by the NBS. We then used these distributions and the yearly value added series for the non-construction secondary industry and the tertiary industry to get estimates of sectoral value added for the other seven sectors of interest. These estimates, along with the value added series for the primary industry (i.e., agriculture, hunting, forestry and fishing) and the construction sector, yielded series of value added by sector disaggregated into our nine sectors of interest.

Sectoral employment was calculated using data from the NBS. The NBS publishes reliable sectoral employment estimates based on data from a number of labor force surveys and calibrated using data from the different population censuses. Given the availability and reliability of these estimates and that they are based on and calibrated using data from the different rounds of population censuses, we decided to use these employment series to get our sectoral employment estimates. In some cases, we aggregated the NBS’ employment series to get sectoral employment at the level we wanted.<sup>28</sup>

While value added and employment data disaggregated by sector for China and Turkey were relatively easy to compile,

collecting data for African countries presented more challenges. Even where value added data are reported in a relatively standard way in Africa, the same is rarely true about employment data. Data on employment by sector in many sub-Saharan countries are sparse, inconsistent, and difficult to obtain. Nevertheless, there are a number of sub-Saharan African countries for which data on value added and employment by sector are available, or can be estimated. Our African sample includes Ethiopia, Ghana, Kenya, Malawi, Mauritius, Nigeria, Senegal, South Africa, and Zambia and covers almost half of total sub-Saharan population (47%) and close to two thirds of total sub-Saharan GDP (63%).<sup>29</sup>

The particular steps to get estimates of sectoral value added and employment for these sub-Saharan countries varied due to differences in data availability. Once again, we followed Timmer and de Vries' (2007, 2009) methodology as closely as possible to ensure comparability with data from

the 10-Sector Database. We used data on sectoral employment from population censuses and complemented this with data from labor force surveys and household surveys. We took care to make sure that employment in the informal sector was accounted for. In some cases, this meant using data from surveys of the informal sector (when available) to refine our estimates of sectoral employment. We used data on value added by sector from national accounts data from different national sources and complemented them with data from the UN's national accounts statistics in cases where national sources were incomplete or we found inconsistencies. Due to the relative scarcity of data sources for many of the sub-Saharan economies in our sample, our data are probably not appropriate to study short-term (i.e., yearly) fluctuations, but we think they are still indicative of medium-term trends in sectoral labor productivity.
